NUST MISiS

October 2021

System of units $c = \hbar = 1$

In this system of units the only nontrivial dimension is the dimension of mass M . Time and length have the dimension of $1/M$. This follows immediately from the definition of the Planck constant $E = \hbar\omega$, so for the dimensions which are denoted by square brackets one can write

$$[\hbar] = \left[\frac{ML^2}{T} \right], \quad [c] = \left[\frac{L}{t} \right], \quad (1)$$

so if $c = \hbar = 1$ then $[L] = [T] = \left[\frac{1}{M} \right]$. For the particle with mass M the value of $1/M$ is the *Compton wavelength*.

System of units $c = \hbar = 1$

$$1 \text{ GeV} = 1.6 \cdot 10^{-10} \text{ J} = 1.6 \cdot 10^{-10} \text{ kg m}^2 / \text{s}^2$$

(Problem: Find in J the electron energy $m = 0.511 \text{ MeV}$ in the potential $\Delta U 10^9 \text{ V}$)

writing down $E = mc^2 \Rightarrow m$ at $c=1$

$$1 \text{ GeV} = m \cdot 9 \cdot 10^{16} \text{ m}^2/\text{s}^2 = 1.6 \cdot 10^{-10} \text{ kg m}^2/\text{s}^2$$

$$1 \text{ GeV}/c^2 = 1.78 \cdot 10^{-27} \text{ kg}$$

then $E^2 = p^2 + m^2$ (not $E^2 = \vec{p}^2 c^2 + m^2 c^4$)

Compton wavelength is measured in inverse GeV (in the following [dimension] is indicated in square brackets)

$$[\text{m}] \quad \lambda = \frac{\hbar}{mc} \Rightarrow \frac{1}{m}, \quad \text{GeV}^{-1} = 0.197 \cdot 10^{-15} \text{ m}$$

$$= 0.197 \text{ fm}, \quad 1 \text{ fm} = 10^{-15} \text{ m}$$

Time is also measured in inverse GeV:

$$[\text{s}] \quad \frac{\lambda}{c} = \frac{\hbar}{mc^2} \Rightarrow \frac{1}{m}, \quad \text{GeV}^{-1} = 6.582 \cdot 10^{-25} \text{ s}$$

System of units $c = \hbar = 1$

<i>Observable</i>	kg, m, s	GeV, \hbar , c	$\hbar=c=1$
Time	s	$(\text{GeV}/\hbar)^{-1}$	GeV^{-1}
Length	m	$(\text{GeV}/\hbar c)^{-1}$	GeV^{-1}
Square	m^2	$(\text{GeV}/\hbar c)^{-2}$	GeV^{-2}
Energy	$\text{kg m}^2 \text{s}^{-2}$	GeV	GeV
Momentum	$\text{kg m}^2 \text{s}^{-1}$	GeV/c	GeV
Mass	kg	GeV/c^2	GeV

Таблица: Units in the system $c=\hbar=1$ in comparison with SI. Transformation factors. Useful relation

$$\hbar c = 0.197 \text{ GeV} \times \text{fermi}$$

Lecture 4, slide 7. Lagrangian symmetries and conserved currents.

Action of a scalar field $\varphi(x)$ in a general form ($\partial_\mu = \partial/\partial x_\mu$)

$$S = \int \mathcal{L}(\varphi^I(x), \frac{\partial\varphi^I(x)}{\partial x_\mu}) d^4x \quad (2)$$

where the index I corresponds to a set of fields. In the following we use the notation $\frac{\partial\varphi^I(x)}{\partial x_\mu} = \varphi^I_{,\mu}$. Variation of action (1)

$$\delta S = \int \left[\frac{\partial\mathcal{L}}{\partial\varphi^I} \delta\varphi^I + \frac{\partial\mathcal{L}}{\partial\varphi^I_{,\mu}} \partial_\mu(\delta\varphi^I) \right] d^4x \quad (3)$$

sum over I is taken. Integrating the second term by parts and assuming that variations of fields are zero at the boundary of a space-time domain we get

$$\delta S = \int \left[\frac{\partial\mathcal{L}}{\partial\varphi^I} \delta\varphi^I - \partial_\mu \frac{\partial\mathcal{L}}{\partial\varphi^I_{,\mu}} \right] (\delta\varphi^I) d^4x \quad (4)$$

so I equations of motion for the fields φ^I follow from the requirement $\delta S = 0$

$$\partial_\mu \frac{\partial\mathcal{L}}{\partial\varphi^I_{,\mu}} - \frac{\partial\mathcal{L}}{\partial\varphi^I} = 0. \quad (5)$$

Lecture 4, slide 7. Lagrangian symmetries and conserved currents.

Let us consider infinitesimal transformations of the general form

$$\varphi^I \implies \varphi'^I = (\delta^{IJ} + \epsilon^a t_a^{IJ}) \varphi^J \quad (6)$$

where ϵ^a are infinitesimal transformation parameters and t_a^{IJ} are some numerical parameters characterizing the transformation. Then variations of the field and the field derivative are

$$\delta\varphi^I = \epsilon^a t_a^{IJ} \varphi^J, \quad \delta\varphi_{,\mu}^I = \epsilon^a t_a^{IJ} \partial_\mu \varphi^J \quad (7)$$

so variation of the Lagrangian when we shift the field by $\delta\varphi^I$ and the derivative of field by $\delta\varphi_{,\mu}^I$ looks as

$$\frac{\partial\mathcal{L}}{\partial\varphi^I} \delta\varphi^I + \frac{\partial\mathcal{L}}{\partial\varphi_{,\mu}^I} t_a^{IJ} \partial_\mu \varphi^J = 0 \quad (8)$$

and is equal to zero due to invariance of \mathcal{L} with respect to transformations (5). Here we omitted the independent parameters ϵ^a . Using the field equation (4) we can write the derivative $\partial_\mu(\partial\mathcal{L}/\partial\varphi_{,\mu}^I)$ instead of $\partial\mathcal{L}/\varphi^I$ in the first term of (7). After that sum of two terms forms the full derivative which expresses the conservation of current

$$J_\mu^a = \frac{\partial\mathcal{L}}{\partial\varphi_{,\mu}^I} t_a^{IJ} \partial_\mu \varphi^J, \quad \partial_\mu J_\mu^a = 0. \quad (9)$$

Lecture 4, slide 7. Lagrangian symmetries and conserved currents.

Problem 1 starts from the Lagrangian for complex scalar field

$$\mathcal{L} = \partial_\mu \varphi \partial_\mu \varphi^* - m^2 \varphi \varphi^* \quad (10)$$

where φ and φ^* are considered as independent fields, so φ^I , $I = 1, 2$ above denotes φ, φ^* . This Lagrangian is invariant with respect to

$$\varphi \implies \varphi' = e^{i\epsilon} \varphi, \quad \varphi^* \implies \varphi'^* = e^{i\epsilon} \varphi^* \quad (11)$$

so the following calculation of the conserved current (7) is straightforward.

Problem 1a: Show that the charge Q defined as

$$Q = \int J_0 d^3x \quad (12)$$

is conserved, $\partial_0 Q = 0$. Calculate Q for the case of the solution of (3) which has the form $\varphi = N e^{-i(kr - \omega t)}$ (plane wave, $\omega^2 = k^2 + m^2$), where N is the normalisation factor defined by normalisation of the energy of the field. Calculate N . Calculate the value of Q for this case.

Lecture 4, slide 11. $SU(2)$ symmetry and resonance decays. C -parity

(1) Mesons and baryons form isotopic multiplets which are described by irreducible representations of $SU(2)$ group

(2) Infinitesimal operators t_i of these representations, $[t_i, t_j] = i\epsilon_{ijk}t_k$ are called the isotopic spin operators. The operator $t^2 = t_1^2 + t_2^2 + t_3^2$, $t^2 = I(I+1)E$, E is unit operator, I is the isotopic spin of the multiplet. Electric charge of a particle - component of an isotopic multiplet - is expressed by means of t_3 and hypercharge Y

$$Q = t_3 + \frac{Y}{2} \quad (13)$$

which is known as Gell-Mann - Nishijima formula.

Examples

Proton and neutron form an isotopic doublet $I=1/2$ under the name nucleon. In

terms of $SU(2)$ they are described by covariant isotopic spinor $\phi_\alpha = \begin{pmatrix} \phi_1 \\ \phi_2 \end{pmatrix}$ defined

in the basis e^α ($e^\alpha e^\beta = \delta^{\alpha\beta}$)

$$e^1 = \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \quad e^2 = \begin{pmatrix} 0 \\ 1 \end{pmatrix}$$

basis vectors are transformed as $e^{\alpha'} = U_{\beta\alpha} e^\beta$, so $\varphi'_\alpha = U_{\alpha\beta} \varphi_\beta$ (fundamental representation, $SU(2)$ transformation is identical to group representation). We can write

$$p = \begin{pmatrix} 1 \\ 0 \end{pmatrix} \otimes \psi(x), \quad n = \begin{pmatrix} 0 \\ 1 \end{pmatrix} \otimes \psi(x), \quad \text{or} \quad N = \begin{pmatrix} p \\ n \end{pmatrix}$$

Lecture 4, slide 11. $SU(2)$ symmetry and resonance decays.

π^\pm and π^0 mesons form an isotopic triplet $I=1$ and are described by the second rank isotopic spinor transformed as $U \otimes U^*$, with one upper and one lower index. Such spinor is a sum of a spinor with zero trace and Kronecker term δ_b^a :

$$\varphi_b^a = (\varphi_b^a - \frac{1}{2}\delta_b^a \varphi_c^c) + \frac{1}{2}\delta_b^a \varphi_c^c,$$

which form two $SU(2)$ invariant subspaces. Zero trace basis looks as

$$e_2^1, \quad \frac{1}{\sqrt{2}}(e_1^1 - e_2^2), \quad e_1^2$$

and the one-dimensional space basis vector

$$\frac{1}{\sqrt{2}}(e_1^1 + e_2^2)$$

is orthogonal to the three basis vector for zero-trace subspace. Matrix form looks as

$$e_+ = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}, e_0 = \begin{pmatrix} \frac{1}{\sqrt{2}} & 0 \\ 0 & -\frac{1}{\sqrt{2}} \end{pmatrix}, e_- = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}$$

Lecture 4, slide 11. $SU(2)$ symmetry and resonance decays.

so for the triplet of π -mesons we have the form

$$\pi_b^a = \begin{pmatrix} \frac{1}{\sqrt{2}}\pi^0 & \pi^+ \\ \pi^- & -\frac{1}{\sqrt{2}}\pi^0 \end{pmatrix}$$

Such form is very convenient to define charge conjugation C , when

$$\pi^+ \rightarrow \pi^-, \quad \pi^- \rightarrow \pi^+, \quad \pi^0 \rightarrow \pi^0$$

which can be written in the matrix form

$$\pi_b^a \rightarrow \pi_a^b \quad \text{or, equivalently} \quad C\pi_b^a C^+ = \pi_a^b$$

Important $SU(2)$ transformation is the *charge symmetry transformation* where the matrix is

$$CS = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} = i\sigma_2$$

Matrix elements should be invariant under CS. Such transformation for the nucleon isotopic doublet

$$CS \begin{pmatrix} p \\ n \end{pmatrix} = \begin{pmatrix} n \\ -p \end{pmatrix}$$

Lecture 4, slide 11. $SU(2)$ symmetry and resonance decays.

CS transformation for the pion triplet

$$CS \begin{pmatrix} \frac{1}{\sqrt{2}}\pi^0 & \pi^+ \\ \pi^- & -\frac{1}{\sqrt{2}}\pi^0 \end{pmatrix} CS^+ = \begin{pmatrix} -\frac{1}{\sqrt{2}}\pi^0 & -\pi^- \\ -\pi^+ & \frac{1}{\sqrt{2}}\pi^0 \end{pmatrix}$$

Important point is the relation between components of the isotopic spinor π_b^a and 3-vectors. Let us expand π_b^a in the basis of Pauli matrices

$$\pi_a^b = \frac{1}{\sqrt{2}}(\tau_i)_a^b V_i, \quad (2A)$$

then it is well-known that $V_i = (V_1, V_2, V_3)$ transform as the 3-vector components which can be easily found:

$$V_i = \frac{1}{\sqrt{2}}(\tau_i)_b^a \varphi_a^b = \frac{1}{\sqrt{2}}Sp(\tau_i \varphi) \quad (2B)$$

. Normalization condition

$$V_i V_i^* = (\varphi^+)_b^a \varphi_a^b = Sp(\varphi^+ \varphi).$$

Using these formulae a relation between e_+, e_0, e_- and the Cartesian basis e_x, e_y, e_z for 3-vectors V_i can be easily found

$$e_+ = \frac{1}{\sqrt{2}}(e_x + ie_y), e_0 = e_z, e_- = \frac{1}{\sqrt{2}}(e_x - ie_y)$$

Lecture 4, slide 11. $SU(2)$ symmetry and resonance decays.

To write $SU(2)$ invariant Lagrangian for nucleon- π interaction, compose the form $\bar{N}^a \pi_d^c N_b$ and take a sum over upper and lower pair of indices, so we have *line* \times *matrix* \times *column*, which is $SU(2)$ scalar. Then the Lagrangian ($g_{\pi NN} \sqrt{2}$ - coupling constant)

$$L_{\pi NN} = g_{\pi NN} \sqrt{2} \bar{N}^a \pi_a^b N_b$$

or in terms of 3-vector V_i

$$L_{int} = g_{\pi NN} \bar{N} \tau_i \pi_i N$$

Substituting here matrix expressions we find an explicit form

$$L_{\pi NN} = g_{\pi NN} [\sqrt{2} \bar{p} n \pi^+ + \sqrt{2} \bar{n} p \pi^- + (\bar{p} p - \bar{n} n) \pi^0]$$

Less trivial example: decay of $f^0(1270)$ meson ($T=0$) to the two π -mesons ($T=1$), $f^0 \rightarrow \pi(p_1) \pi(p_2)$, where p_1 and p_2 are 4-momenta. $SU(2)$ invariant matrix element of this decay has the form

$$M(f^0 \rightarrow \pi\pi) = g_{f\pi\pi} f^0 \pi_b^a \pi_a^b = g_{f\pi\pi} [\pi^+(p_1) \pi^-(p_2) + \pi^-(p_1) \pi^+(p_2) + \pi^0(p_1) \pi^0(p_2)]$$

so the probability of the channel $\pi^+ \pi^-$ is higher by a factor of 2 than of the channel $\pi^0 \pi^0$

$$\frac{BR(f^0 \rightarrow \pi^+ \pi^-)}{BR(f^0 \rightarrow \pi^0 \pi^0)} = 2$$

Problem 2. $SU(2)$ symmetry and resonance decays.

Note that $M(f^0 \rightarrow \pi\pi)$ is C -invariant only if the C -parity of the f^0 meson is equal to +1. Indeed, under C transformation

$$f^0 \rightarrow f^0, \quad \pi_b^a \pi_a^b \implies \pi_a^b \pi_b^a \quad \text{identical to} \quad \pi_b^a \pi_a^b$$

This matrix element respects also Bose statistics, since 2π are in D -state (f^0 has spatial spin 2 and P parity +1) so the spatial wave function (not written in the formulas above) is symmetric under $p_1 \rightarrow p_2, p_2 \rightarrow p_1$ and also the isotopic matrix element.

Brief denomination of Particle Data: $f^0(1270) I^G(J^{PC}) = 0^+2^{++}$.

For example, $\varphi(1020)$ meson, $I^G(J^{PC}) = 0^-1^{--}$, decay to 2π is described by the matrix element of the same structure, as above. However, under C transformation $\varphi \rightarrow -\varphi$, so conservation of C invariance does not allow $\varphi \rightarrow \pi\pi$.

Problem 2, Lecture 4 Matrix element of $\rho(1450)$ which is isotopic triplet $I=1$, $I^G(J^{PC}) = 1^+1^{--}$, $C\rho_b^a C^+ = -\rho_a^b$ to $\pi\pi$ is described by $SU(2)$ invariant matrix element, invariant under C :

$$M(\rho \rightarrow \pi\pi) = g\rho_b^a \pi_c^b \pi_a^c$$

This matrix element defines relations between decay channels.

Problem 2. $SU(2)$ symmetry and resonance decays.

The image shows a screenshot of the Particle Data Group (PDG) website. At the top left is the PDG logo with the text 'particle data group'. To the right is the title 'Summary Tables' in red. Below the logo is a navigation bar with links: 'HOME', 'pdgLive', 'Summary Tables', 'Reviews, Tables, Plots', and 'Particle Listings'. The main heading is '2020 Review of Particle Physics'. Below this, a citation is provided: 'Please use this CITATION: P.A. Zyla et al. (Particle Data Group), Prog. Theor. Exp. Phys. 2020, 083C01 (2020). Cut-off date for this update was January 15, 2020.' A 'Search Tables' button is visible. The page lists several sections: 'Gauge and Higgs Bosons (gamma, g, W, Z, ...)', 'Leptons (e, mu, tau, ... neutrinos ...)', 'Quarks (u, d, s, c, b, t, b', t', Free)', 'Mesons' with a 'contents' link, 'Baryons' with a 'contents' link, 'Searches not in Other Sections (SUSY, Compositeness, ...)', and 'Tests of Conservation Laws'. LIGHT UNFLAVORED MESONS ($S = C = B = 0$)

For $I = 1$ (π , b , ρ , a): $u\bar{d}$, $(u\bar{u} - d\bar{d})/\sqrt{2}$, $d\bar{u}$;
for $I = 0$ (η , η' , h , h' , ω , ϕ , f , f'): $c_1(u\bar{u} + d\bar{d}) + c_2(s\bar{s})$

π^\pm

$$I^G(J^P) = 1^-(0^-)$$

Mass $m = 139.57039 \pm 0.00018$ MeV ($S = 1.8$)

Mean life $\tau = (2.6033 \pm 0.0005) \times 10^{-8}$ s ($S = 1.2$)

$c\tau = 7.8045$ m

π^0

$$I^G(J^{PC}) = 1^-(0^{-+})$$

Mass $m = 134.9768 \pm 0.0005$ MeV ($S = 1.1$)

$m_{\pi^\pm} - m_{\pi^0} = 4.5936 \pm 0.0005$ MeV

Mean life $\tau = (8.52 \pm 0.18) \times 10^{-17}$ s ($S = 1.2$)

$c\tau = 25.5$ nm

$f_2(1270)$

$$I^G(J^{PC}) = 0^+(2^{++})$$

Mass $m = 1275.5 \pm 0.8$ MeV

Full width $\Gamma = 186.7^{+2.2}_{-2.5}$ MeV ($S = 1.4$)

$f_2(1270)$ DECAY MODES

	Fraction (Γ_i/Γ)	Scale factor/ Confidence level	p (MeV/c)
$\pi\pi$	$(84.2^{+2.9}_{-0.9})\%$	$S=1.1$	623

PDG tables – G parity

After C transformation the neutral particles are transformed into themselves, their wave function is not changed (C parity +1) or changes sign (C parity -1). Charged particles are transformed to their antiparticles, so they do not have C -parity. We can generalize the notion of C -parity for (anti)particles from the same isotopic multiplet, combining C transformation and CS transformation, so $G = C \times CS$. For example, C -transformation for π triplet

$$\pi^- \rightarrow \pi^+, \quad \pi^+ \rightarrow \pi^-, \quad \pi^0 \rightarrow \pi^0$$

Under CS transformation described above

$$\pi^- \rightarrow -\pi^+, \quad \pi^+ \rightarrow -\pi^-, \quad \pi^0 \rightarrow -\pi^0$$

Combining C and CS , we have

$$\pi^- \rightarrow -\pi^-, \quad \pi^+ \rightarrow -\pi^+, \quad \pi^0 \rightarrow -\pi^0$$

so G -parity of the pion triplet is -1, or pions are eigenstates of the $C \times CS$ with the eigenvalue -1. G -parity conservation does not allow, for example, $\rho \rightarrow 3\pi$, $\phi \rightarrow 2\pi$ and so on. The value of G is indicated in the standard PDG denomination $I^G(J^{PC})$.
